

Data center power supply monitoring solution

1 General

With the development of data center, the problem of energy consumption is also prominent. Energy management and design of power supply and distribution for data center has been a hot issue. High efficient and reliable power distribution solution for data center is an effective way for improving efficiency of power usage for data center and lowering energy consumption. To realize the energy saving for data center, it is necessary to monitor every load accurately. However, as there are too many load circuits in data center, it is hard for traditional meters to meet the requirements of cost, dimension, installation, construction, etc. Therefore, multi-circuit monitoring device is needed for centralized monitoring for data center.

Acrel AMC16 series multi-circuit monitoring device is specially designed for the power management of center data server in data center. This device is small and exquisite, which can monitor electric parameters and switching state from as many as dozens of circuits besides input circuit and output circuit in a centralized way. It realizes high centralization of monitoring circuits in the dimension of traditional meter.

2 Ordering example

2.1 Model: AMC16MA

Technical requirements: Input voltage AC220V, input current AC 5A, self-setting transformer ratio, outlet current transformer ratio AC100A/20mA, 2 inlet testing and 36 single phase (or 12 3-phase) outlet testing, 1 switching output.

Communication protocol: RS485 port Modbus/RTU protocol

Power supply:AC220V

(2)Model:AMC16MD

Technical requirements: input voltage DC 48V, input current DC50mA with self-setting. 42 DC testing, 1 switching output.

Communication protocol:RS485 port Modbus/RTU protocol

Power supply:DC48V

2.2 Model:AMC16-E4/A

Technical requirements: Input phase voltage AC220V, input current transformer ratio 2000A/5A(or 200A/10mA), 2 switching input and 1 relay output. Lightning protection 5kA.

Communication protocol: RS485 port Modbus/RTU protocol

Power supply: DC48V

2.3 Model: AMC16-E3

Technical requirements: input line voltage AC 380V, current transformer ratio 2000A/5A, 2 switching input and 1 relay output.

Communication protocol: RS485 port Modbus/RTU protocol

Power supply:AC/DC220V

2.4 Model:AMC16-E4/S

Technical requirements: input phase voltage AC 220V, current transformer ratio 2000A/5A, 2 switching input and 1 relay output.Measuring grid power and gas generator power separately.

Communication protocol:RS485 port Modbus/RTU protocol

Power supply:AC/DC220V

3 *Communication protocol*

This protocol stipulates protocols for the physical connections and communications between AMC16 Series multi-circuit monitoring device and data terminal equipments. The method of communication in this protocol is similar to Modbus-RTU.

3.1 General Description of this Protocol

The protocol used in AMC Series device defines data sequence for address code, function code and check code in a detailed way. These are necessary for specific data exchange. This protocol adopts master-slave for network communication in one communication wire (half duplex communication). This means that in a single communication wire signal will be transmitted in two opposite ways. First, the master computer signal addresses the only terminal equipment (slave computer), and then the response signal from the terminal

equipment returns to the master computer in the opposite direction.

This protocol allowed only in the host (PC, PLC) and the communication between terminal equipment between the terminal equipment, and does not allow the independent data exchange, so that each terminal device does not occupy the communication line in their initialization, and only reached the query response signal of the machine.

Transmission Mode

Data are transmitted in an asynchronous way and measured by bytes. The communication between master computer and slave computer is 11-byte format, including 1 start bit, 8 data bits (the least significance bit will be sent first), parity bit and 2 stop bits.

3.2.1 Data Frame Format

Address Code	Function Code	Data Field	CRC Check Code
1 byte	1 byte	n byte	2 bytes

3.2.2 Address Field

Address field is located at the beginning of frame, made up of 1 byte (8-bit binary code), 0 ~ 255 in decimal system, only 1 ~ 247 used in our system, retaining other addresses. These bits set addresses for the terminal equipment designated by users. The equipment will receive data from master computer connected to it. The address for the terminal equipment must be unique. Only the addressed terminal will respond to the query with this address. When the terminal responds a message, the address data in response will tell the master computer which terminal is communicating with it.

3.2.3 Function Field

Function field code tells the addressed terminal to carry out what function. The following table shows the function codes used in this series device, their definition and functions.

Code	Definition	Operation
03	Read Register	Acquire current binary system value in one or more register.
16	Multi-register	Set binary system value into a series multi-register.

3.2.4 Data field

Data field contains the data terminal needs to carry out specific functions or the data terminal collects when responding to a query. The data can be values, addresses or set parameters. For example, when function field code tells a terminal to read a register, data field needs to tell from which register and how many data to read. The embedded data and addresses vary with types and the contents in slave computers.

3.2.5 Check Field

This field allows master computer and terminals to check the errors in data transmission. Sometimes, due to electric noise and other interference, data can be changed when transmitted from one equipment to

another. Error check can ensure that master computer or terminals will not respond to the changed data in transmission. This enhance the safety a

3.2.6 Error Checking Method

Error check field takes 2 bytes including a 16-bit binary value. CRC value is calculated by transmission equipment and then is added to data frame. Data receiving equipment will recalculate the CRC value when receiving the data and then compare them with the value in CRC field. If there is difference between the two values, then errors occur.

When CRC is in operation, it presets a 16-bit register all as 1 first and then calculate 8 bits of each byte in data frame and the current value in the register consecutively. Only the 8 bits in each byte engender CRC. Start bit, stop bit and parity bit won't affect CRC. When engendering CRC, the 8 bits in each byte will do XOR calculation with the values in the register and the result will shift towards low bit and high bit will be supplemented by 0. LSB will shift out and check. If LSB is 1, this register will do XOR calculation with a preset fixed value(0A001H) and if LSB is 0, then there is no related operation.

The above operation repeats until 8 bit-shifting is completed. When the last bit shift(the 8th bit) is completed, the next 8-bit byte will do XOR calculation with the current value in register and in the same way do 8 bit shifts. After all the bytes in the data frame finish the above-mentioned operation, the final value is CRC value.

3.3 Description of Function Code

3.3.1 Function Code 02H: Read discrete magnitude input

This function code reads the consecutive state of discrete input from 1 to 2000.The requesting PDU designating the detailed starting address, which is the first designated input address and input no. Addressing input starts from 0. Therefore, addressing input 1-16 will be 0-15. According to every bit in the data field, the discrete input in the responding message shall be taken as an input. Indication status will be 1=ON and 0=OFF. The LSB (lowest bit) of the first data byte is included in the addressing input in query. Repeat the operation to other input until the high bit end in this byte and in the following bytes the order will be from low bit to high bit. If the returned input quantity is not the

The example below is from the 01 number from the machine readable DI7 ~ 10 consecutive switch state DI16

The HOST Sends		Send Information	From the machine returns	Returns Information
Address code		01H	Address code	01H
Function code		02H	Function code	02H
The starting address	high byte	00H	The number of bytes	02H
	Low byte	06H	Input of state14-7	3FH
Number of bytes output	High byte	00H	Input of state16-15	02H

	Low byte	0AH	CRC check code	Low byte	29H
CRC check code	low byte	18H		High byte	89H
		High byte	0CH		

The discrete input state 14-7 said sixteen hexadecimal byte value 3F or binary 00111111. The 14 is the input Bytes of MSB, 7 input is the byte LSB

The discrete input state 16-15 said sixteen hexadecimal byte values 02, or binary 00000010. Input 15 is LSB, zero fill the remaining bits in the last data byte

3.3.2 Function Code 03H: Read Register

This function allows users to obtain the data collected and recorded by equipment and system parameters. There is no limit to the number of data for master to query in one time. But it can't exceed the defined address range.

The following example is the data collected from No. 01 slave computer(each address takes 2 bytes in the data frame) UA, UB, UC. The address for UA is 0011H, for UB, 0012H and for UC, 0013H.

Master Sending		Message	Return from Slave		Returned message
Address Code		01H	Address Code		01H
Function Code		03H	Function Code		03H
Start Address	High Byte	00H	Number of bytes		06H
	Low Byte	03H	Register Data	High Byte	0EH
Num of Registers	High Byte	00H		Low Byte	EEH
	Low Byte	03H	Register Data	High Byte	0EH
CRC Check Code	Low Byte	F5H		Low Byte	E8H
	High Byte	CBH	Register Data	High Byte	0EH

				Low Byte	E9H
			CRC checking code	Low Byte	8FH
				High Byte	7EH

3.3.3 The function code 06H: write a single register

The content of the function code 06H allows the user to change a single register, the instrument system parameters, the switch output state can use this function number written

The following example is preset address is 01 meters and switch quantity output DO. Switch output state register address 0045H, the corresponding DO closed data for 0x01.

HOST SENDS		SEND INFORMATION	From the machine returns		RETURNS INFORMATION
Address code		01H	Address code		01H
FUNCTION CODE		06H	FUNCTION CODE		06H
The starting address	HIGH BYTE	00H	The starting address	HIGH BYTE	00H
	LOW BYTE	45H		LOW BYTE	45H
0045H to write data	HIGH BYTE	00H	read-in data	HIGH BYTE	00H
	LOW BYTE	01H		LOW BYTE	01H
CRC Check Code	LOW BYTE	59H	CRC Check Code	LOW BYTE	59H
	HIGH BYTE	DFH		HIGH BYTE	DFH

3.3.4 Function Code 10H: Write multi-register

Function code 10H allows users to alter the contents in several registers. System parameters and switch output state can be written in by this function. At most, 16 (32-bit) data can be written in at a time.

The following example shows the switch signal DO from the meter with preset address 01. The address

for switch output state indicator register is 0045H. The 1st bit is for DO.

Master Sending		Message sent	Return From Slave		Message returned
Address Code		01H	Address Code		01H
Function Code		10H	Function Code		10H
Start Address	High Byte	00H	Start Address	High Byte	00H
	Low Byte	45H		Low Byte	45H
Num. of Registers	High Byte	00H	Num. of Registers	High Byte	00H
	Low Byte	01H		Low Byte	01H
Num. of bytes		02H	CRC checking code	Low Byte	10H
0045H Data to be written in	High Byte	00H		High Byte	1CH
	Low Byte	01H			
CCRC check code	Low Byte	69H			
	High Byte	05H

Note : 1The above address table is applicable to all devices. Harmonic data apply with H model

2、 Electric power communication data is 1 times side data, unit 0.01kWh

EX:Read the address of the 0x0DH value is 0x1234H, the read address of the 0x0EH value is 0x5678H, the actual primary side power value is 0x12345678H (3054198.96kWh).

3、 The above address table register address value by 16 hexadecimal

4、 Loop phase according to the actual current connected phase setting, corresponding relation between A, B, C for the corresponding to 1, 2

3、 Beyond the scope of the recovery for the default parameters. Example: Outlet line 1, the 2 current respectively is A, B phase load, 0x190H address parameters should be set to 0x0201H, power and electric energy or will be unable to accurately measure 1, 2Outlet line circuit.

5、 In actual use, the user must according to the actual use of device models, parameters to read the corresponding address. Users in the read a register parameters, attention should be paid to the parameters of the number of bytes of address the low or high, and pay attention to the numerical representation of (some numerical reading with binary representation, with some numerical notation, some data for signed operands)

6、 Because AMC16MD with external Holzer transformer, there may be deviation, zero the Holzer transformer is therefore, in actual use, the completion of the Holzer sensor and AMC16MD sensor wiring, Holzer after the power load is not put in front, need to adjust the zero point AMC16MD (0x1A4H ~ 0x1CDH), until 1 to zero 42 Road DC current to zero so far.

7、AMC16MD only allows the input signal for the 0-5V current signal, a primary side current value according to the actual communications through the write command set. (0x9DH ~ 0xC6H)

Belt device switch input function, can also support the function code 01H, 02H
